

# **ENSF 381**

# **Full Stack Web Development**

**Lecture 28: Flask**

**Slides: Ahmad Abdellatif, PhD**

**Instructor: Novarun Deb, PhD**

# Outline

- Introduction to Flask.
- Key benefits.
- Routes.
- Dynamic routes.
- HTTP methods.

# What is Flask?

- A lightweight, versatile and extensible web framework for Python.
- Provides essential features and functionality for building web applications, while extensions provide the rest.
- To use Flask, we need to install it by:

```
pip install Flask
```

# Key features

- **Routing:** allows you to define URL patterns and associate them with functions, making it easy to create routes for different parts of your application.
- **Extension Ecosystem:** Flask has a rich ecosystem of extensions that provide additional functionality and integration with third-party services.
- **Web Development Server:** Flask comes with a built-in development server, making it convenient for testing and development.
- **Request and Response Handling:** Flask simplifies handling HTTP requests and responses. You can easily access request data, cookies, and form submissions, and construct responses with various content types.

# Routing

- In web development, routing refers to the mechanism of mapping URLs to specific functions that handle the requested resource.
- The Flask application knows what code it needs to run for each URL requested.
- Allows breaking down the application into smaller, manageable components.
- Improves code readability and maintainability.

# Flask – example

```
# Import the Flask class  
from flask import Flask
```

```
# Create an instance of the Flask class  
app = Flask(__name__)
```

```
# Define a route and the corresponding function  
@app.route('/')  
def index():  
    return 'Hello, World!'
```

```
# Run the application if this script is executed  
if __name__ == '__main__':  
    app.run()
```

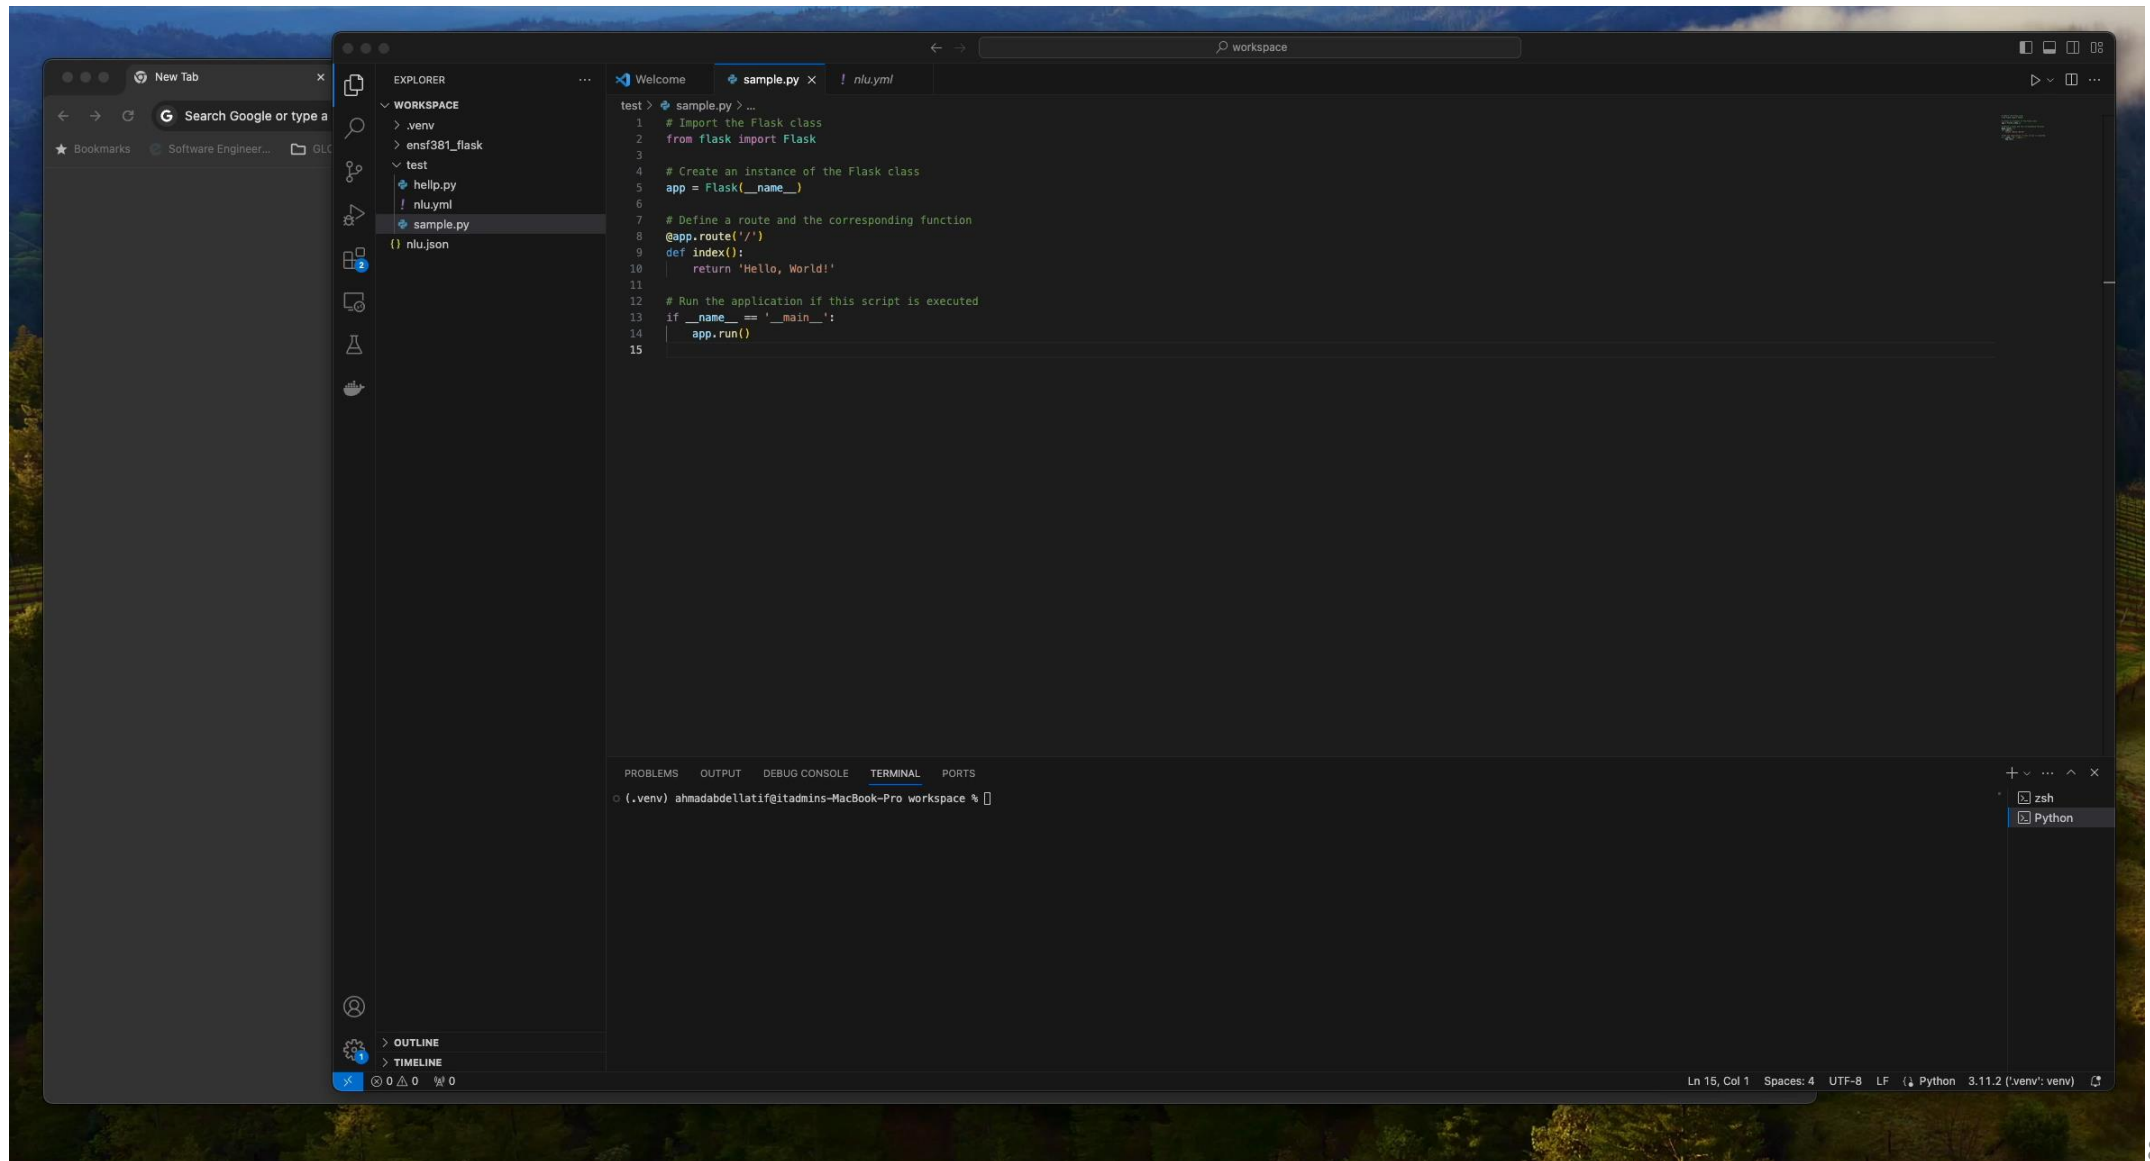

1. **app instance:** create an instance of the Flask class, typically passing `__name__` as an argument.
2. **@app.route() decorator:** associate a URL route with a Python function that corresponds to the route.

# Flask – example

**Running the app:** `run()` method runs the Flask application, and it has four optional parameters:

1. **host:** specifies the hostname to listen on. Defaults to 127.0.0.1 (localhost).
2. **port:** Specifies the port on which the server will listen. The default is 5000, but you can change it if needed.
3. **debug:** when set to True, enables the development mode, which provides more detailed error messages and automatically reloads the server on code changes. The default is false.
4. **options:** allows passing additional configuration options to the underlying server.

# Flask – example

# Routing - example

```
from flask import Flask
```

```
app = Flask(__name__)
```

```
# Define routes and associated functions
```

```
@app.route('/')  
def home():
```

```
    return 'This is Home API'
```

```
@app.route('/articles')  
def articles():
```

```
    return 'This is Articles API'
```

```
@app.route('/about')  
def about():
```

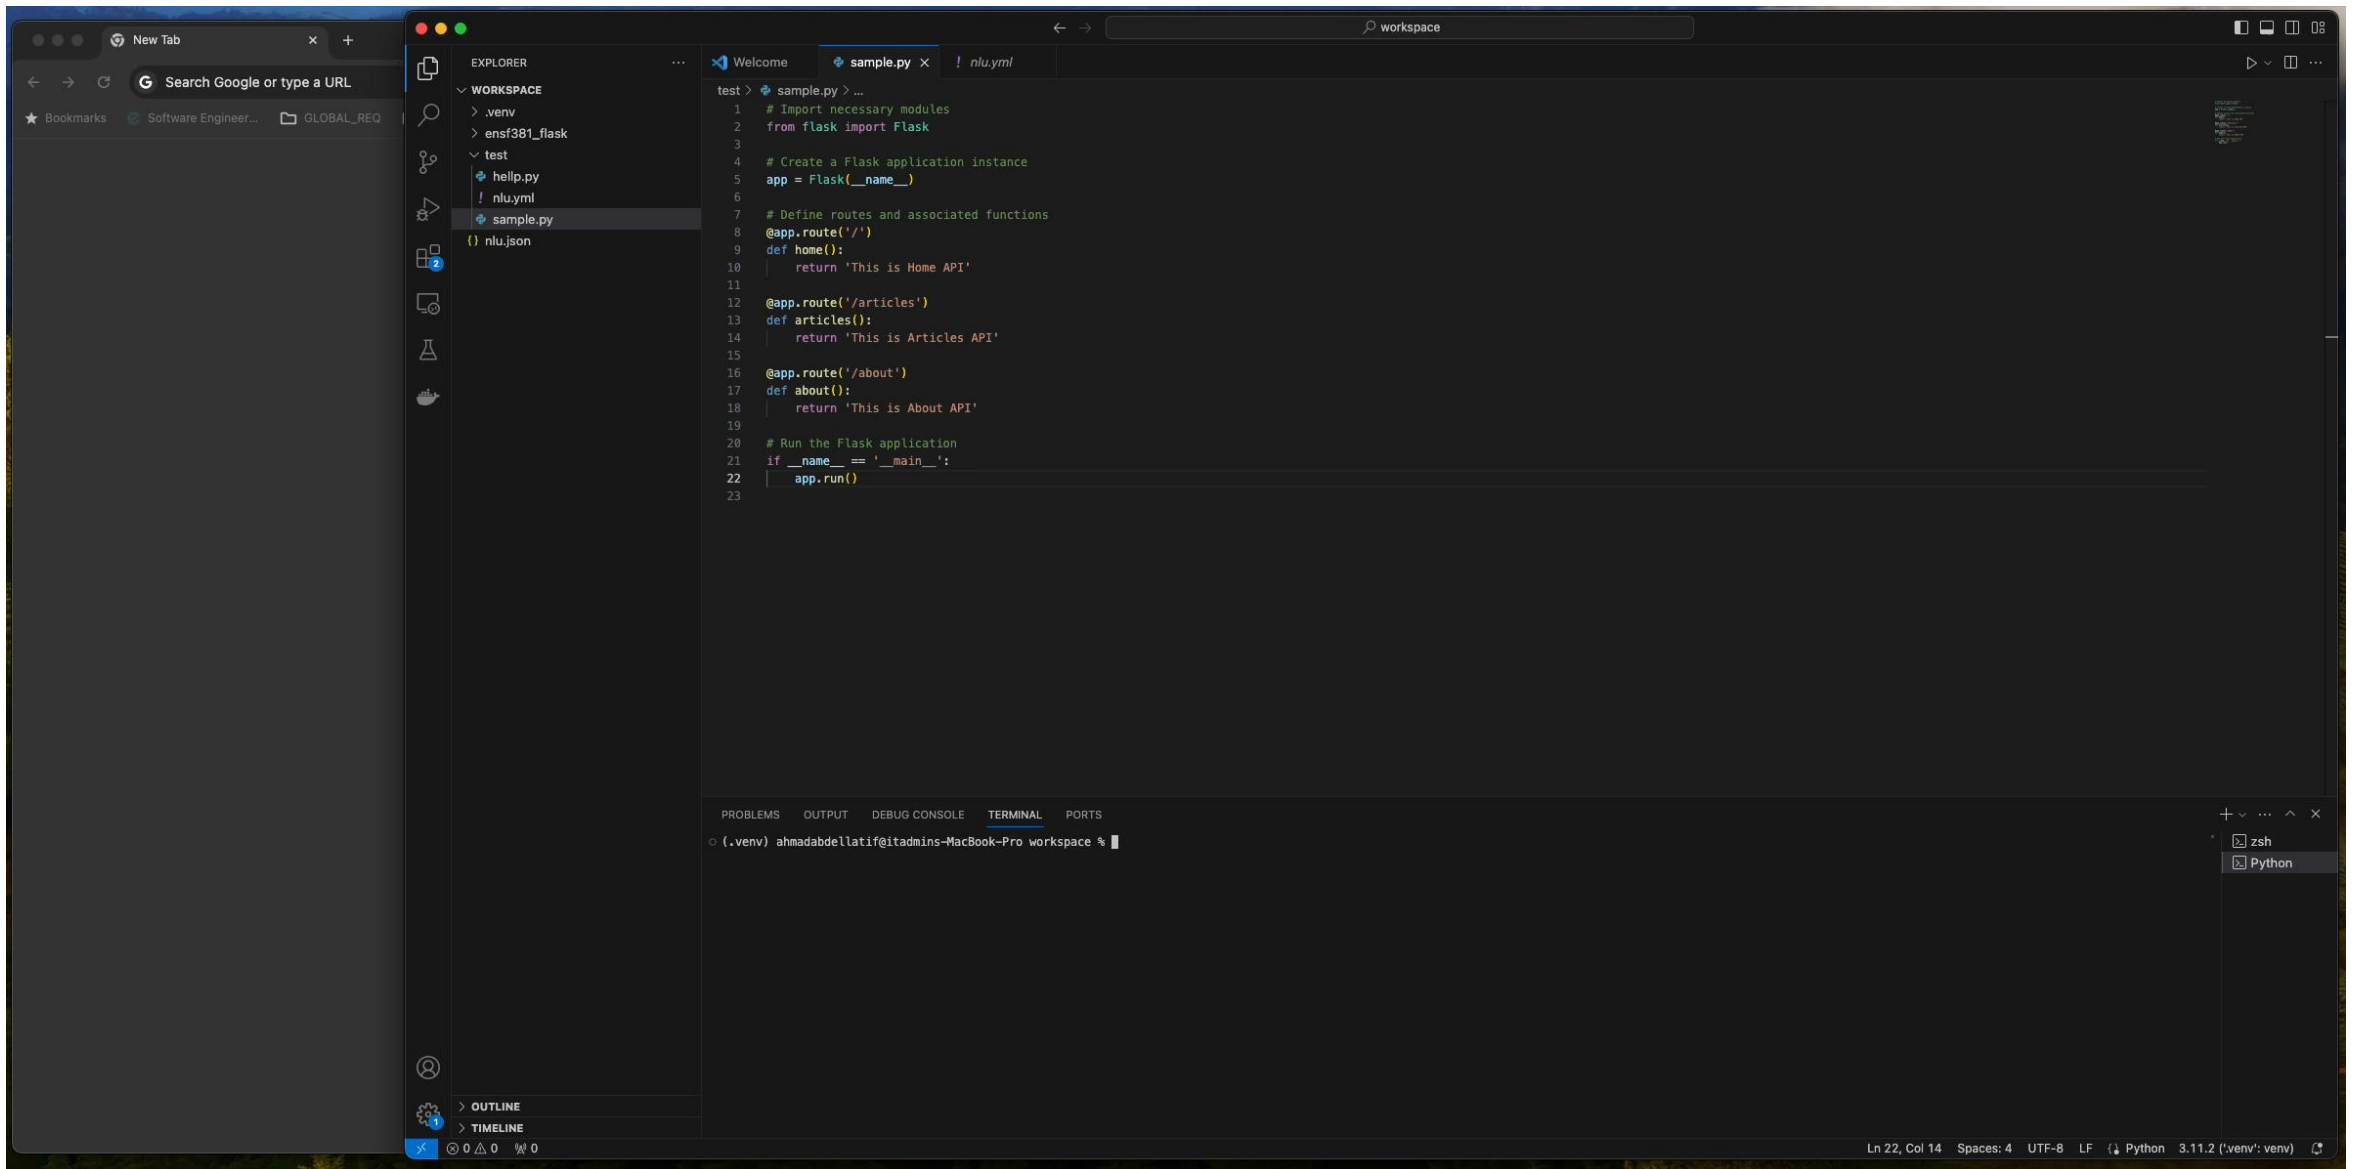

```
    return 'This is About API'
```

```
# Run the Flask application
```

```
if __name__ == '__main__':
```

```
    app.run()
```

# Routing - example

# What is the output of “http://127.0.0.1:5000/test”?

```
from flask import Flask

app = Flask(__name__)

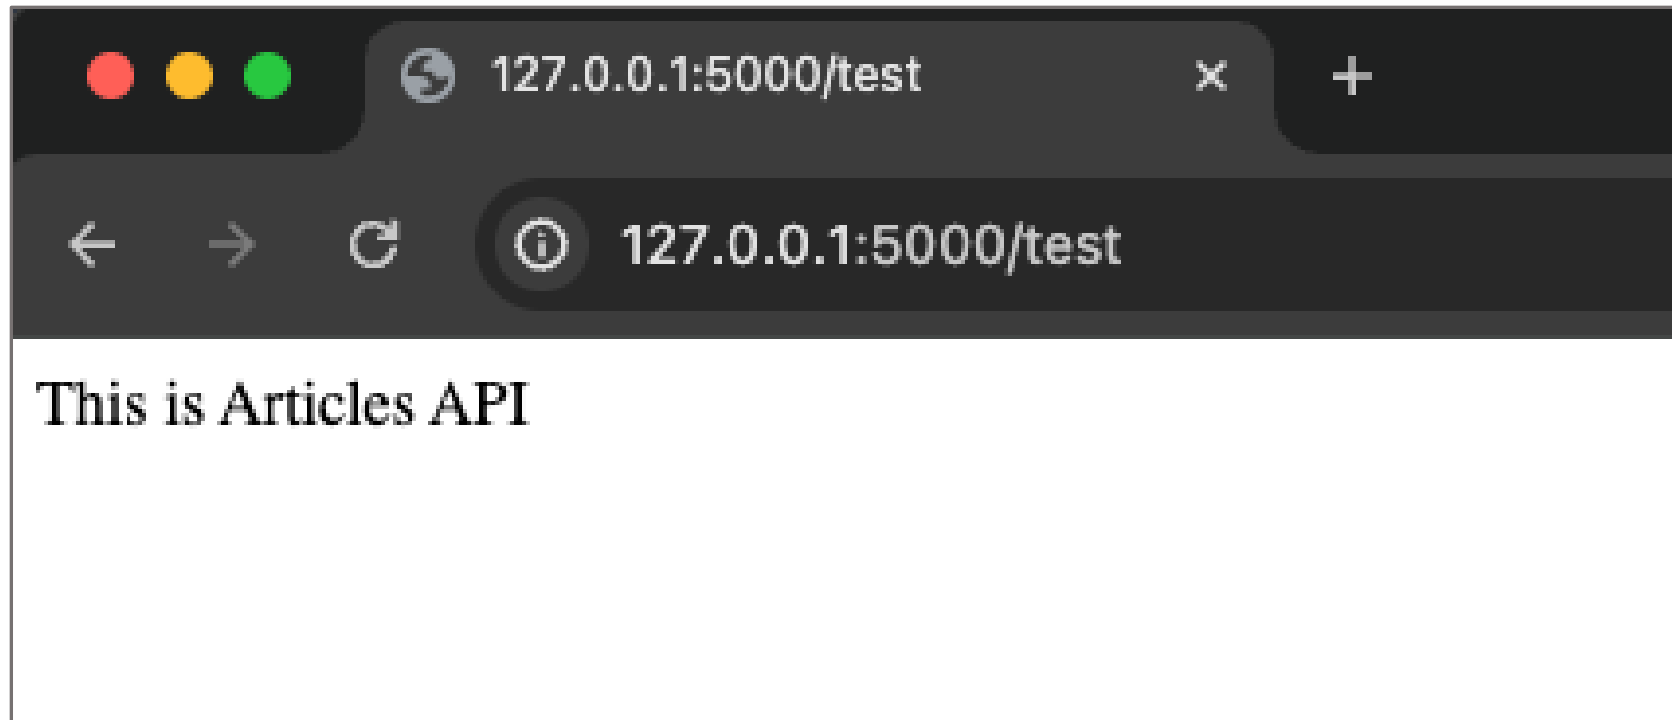

# Define routes and associated functions
@app.route('/')
def home():
    return 'This is Home API'

@app.route('/test')
def articles():
    return 'This is Articles API'

@app.route('/about')
def about():
    return 'This is About API'

# Run the Flask application
if __name__ == '__main__':
    app.run()
```

# What is the output of “http://127.0.0.1:5000/test”?

# Assigning multiple routes to the same function

```
from flask import Flask

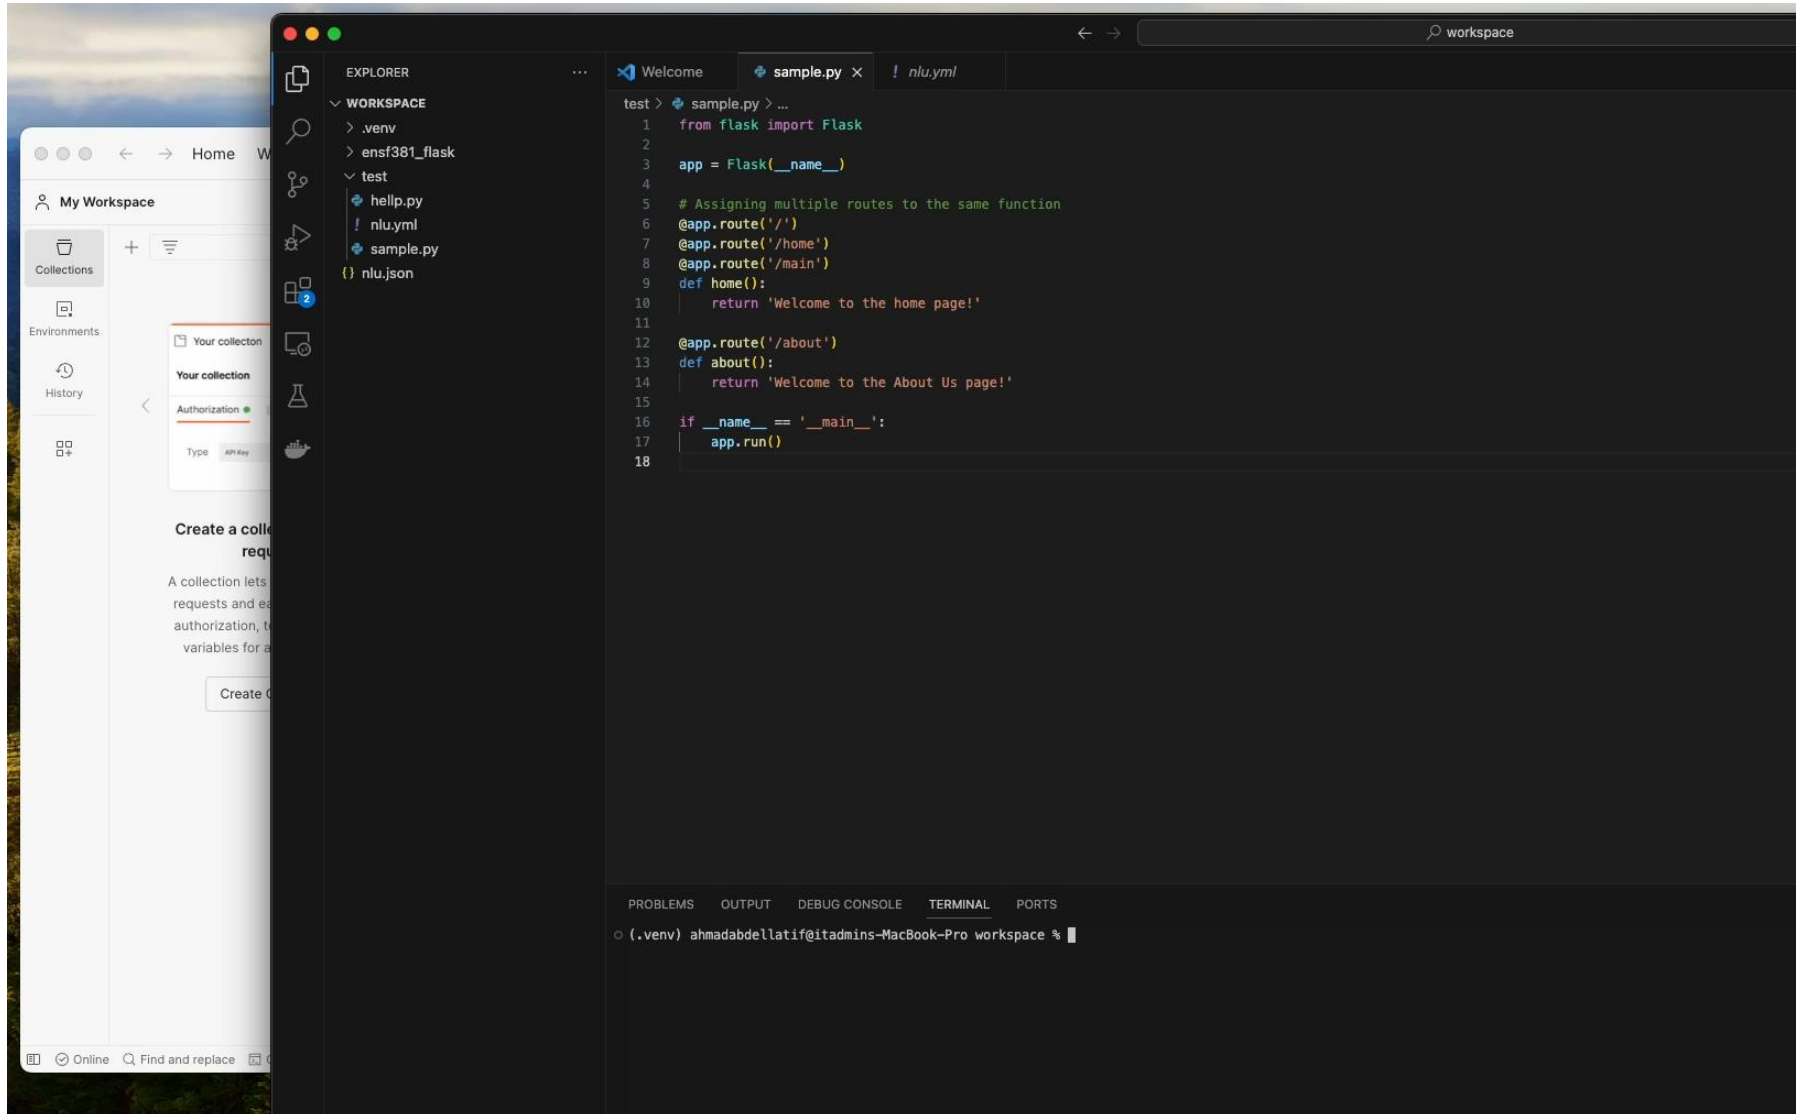

app = Flask(__name__)

# Assigning multiple routes to the same function
@app.route('/')
@app.route('/home')
@app.route('/main')
def home():
    return 'Welcome to the home page!'

@app.route('/about')
def about():
    return 'Welcome to the About Us page!'

if __name__ == '__main__':
    app.run()
```

# Assigning multiple routes to the same function

# Dynamic routes

- A flexible URLs that can handle variable components.
- Instead of defining a fixed set of routes, you can use dynamic route parameters to capture values from the URL.
- Useful when building web applications with variable data, such as user profiles, product pages, or blog posts.
- The variable parts are enclosed in `< >` brackets and act as placeholders for the values that will be extracted from the actual URL during runtime.

# Dynamic routes - example

```
from flask import Flask

app = Flask(__name__)

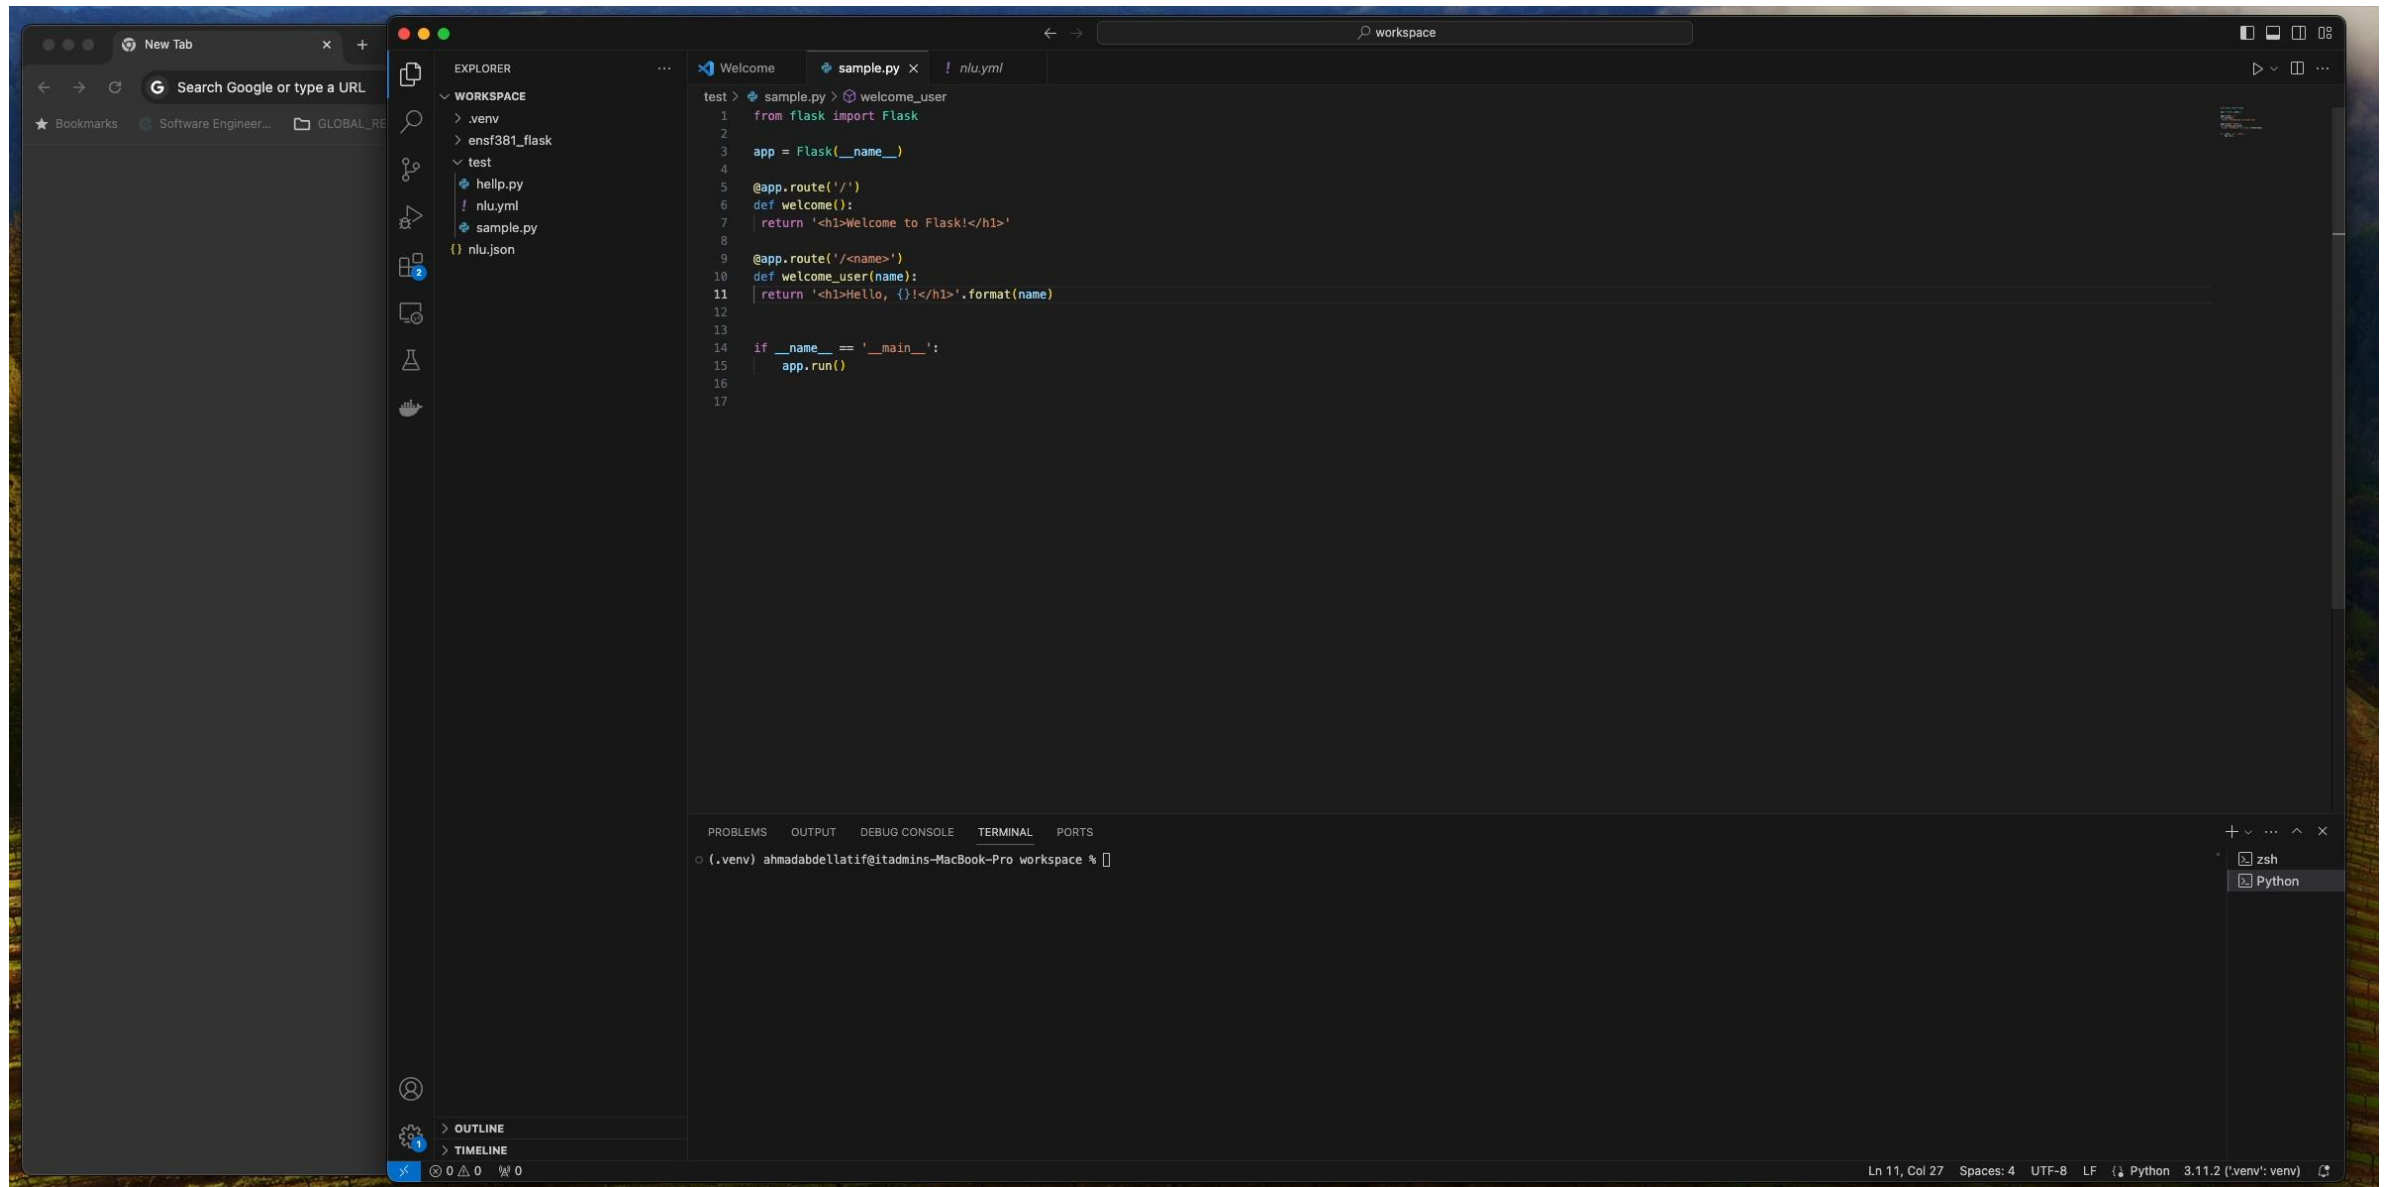

@app.route('/')
def welcome():
    return '<h1>Welcome to Flask!</h1>'

@app.route('/<name>')
def welcome_user(name):
    return '<h1>Hello, {}!</h1>'.format(name)

if __name__ == '__main__':
    app.run()
```

# Dynamic routes - example

# Dynamic routes – example 2

```
from flask import Flask
app = Flask(__name__)

@app.route('/')
def welcome():
    return '<h1>Welcome to Flask!</h1>'

@app.route('/<name>')
def welcome_user(name):
    return '<h1>Hello, {}!</h1>'.format(name)

@app.route('/user/<name>')
def user_point(name):
    return '<h1>Hello {}, from USER API!</h1>'.format(name)

if __name__ == '__main__':
    app.run()
```

# Dynamic routes – example 2

# Recap: HTTP methods

- GET: retrieve data from a specified resource.
  - Example: fetching a webpage, image, or any resource without modifying the server's state.
- POST: submit data to be processed to a specified resource.
  - Example: submitting a form, uploading a file, or making a request that results in the creation of a new resource on the server.
- PUT: update a resource or create a new resource if it does not exist.
  - Example: updating user profile information, uploading a new version of a file.
- DELETE: delete a specified resource.
  - Example: deleting a user account, removing a file from a server.

# HTTP Methods

- Flask supports several HTTP methods that are commonly used in web development.
- Each HTTP method corresponds to a different type of operation you can perform on a resource.

```
from flask import Flask
```

```
app = Flask(__name__)
```

```
@app.route('/home', methods=['GET'])
```

```
def home():
```

```
    return 'This is the home page'
```

Specify the HTTP methods:  
GET, POST, PUT, and DELETE

# HTTP Methods - example

```
from flask import Flask
```

```
app = Flask(__name__)
```

```
# Define a route that handles GET requests
```

```
@app.route('/get_example', methods=['GET'])
```

```
def get_example():
```

```
    return 'This is a GET request example'
```

```
# Define a route that handles POST requests
```

```
@app.route('/post_example', methods=['POST'])
```

```
def post_example():
```

```
    return 'This is a POST request example'
```

```
# Define a route that handles PUT requests
```

```
@app.route('/put_example', methods=['PUT'])
```

```
def put_example():
```

```
    return 'This is a PUT request example'
```

```
# Define a route that handles DELETE requests
```

```
@app.route('/delete_example', methods=['DELETE'])
```

```
def delete_example():
```

```
    return 'This is a DELETE request example '
```

```
if __name__ == '__main__':
```

```
    app.run()
```

# HTTP Methods - example

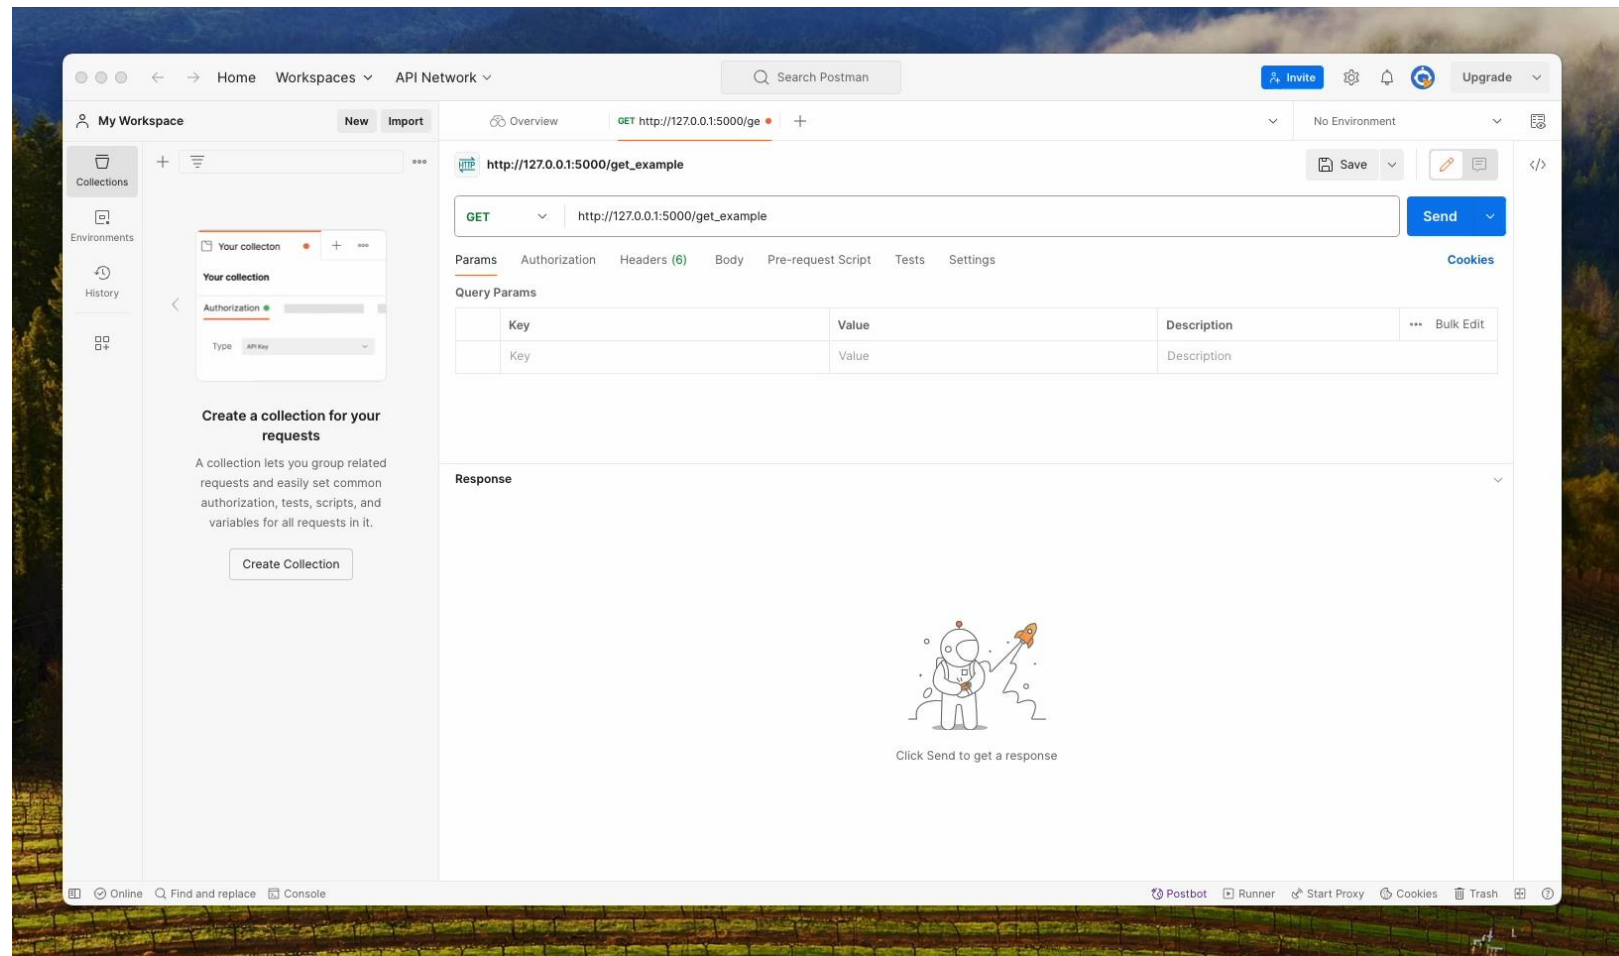

The image shows a screenshot of a development environment with two main windows. The left window is a web browser displaying the 'My Workspace' page, which includes a 'Collections' section and a 'Create a collection for your requests' button. The right window is the Visual Studio Code editor, showing a Python file named 'sample.py' with the following code:

```
test > sample.py > put_example
1 from flask import Flask
2
3 app = Flask(__name__)
4
5 # Define a route that handles GET requests
6 @app.route('/get_example', methods=['GET'])
7 def get_example():
8     return 'This is a GET request example'
9
10 # Define a route that handles POST requests
11 @app.route('/post_example', methods=['POST'])
12 def post_example():
13     return 'This is a POST request example'
14
15 # Define a route that handles PUT requests
16 @app.route('/put_example', methods=['PUT'])
17 def put_example():
18     return 'This is a PUT request example'
19
20 # Define a route that handles DELETE requests
21 @app.route('/delete_example', methods=['DELETE'])
22 def delete_example():
23     return 'This is a DELETE request example'
24
25 if __name__ == '__main__':
26     app.run()
27
```

The bottom of the VS Code window shows the 'TERMINAL' tab with the command prompt: `(.env) ahmadabdelatif@itadmins-MacBook-Pro workspace %`. The status bar at the bottom indicates 'Ln 17, Col 19 Spaces: 4 UTF-8 LF Python'.

# Question

What would be the result when using the HTTP POST method on 'http://127.0.0.1:5000/get\_example'?
